

5. Project Development Phase

User and Role Setup

The development begins by creating the EEE User and the four custom roles. The roles bb1, bb2, bb3, and bb4 are assigned to the test user so that the different access levels can be validated during development.

Creating the Custom Table

The Institution Details table is created with the system name u_institution_details. The required fields are added, including Student Roll Number, Student Name, Faculty Name, Branch, Email, Phone Number, and Description. Sample records are created using different branch values.

READ ACL

The READ ACL is configured as a record ACL for u_institution_details. It is made active and advanced, bb1 is added as the required role, and the Branch condition is set to EEE. The script allows administrators and users with bb1 and denies users who do not satisfy the rule.

CREATE ACL

A separate CREATE ACL is created for the same table. The ACL is active and requires the bb2 role. No data condition is used for this operation.

WRITE ACL

The WRITE ACL is configured as an active record ACL and requires bb3. No data condition is added. This separates record modification permission from the other operations.

DELETE ACL

The DELETE ACL is configured as an active record ACL and requires bb4. No data condition is used. This completes the operation-specific access configuration.

Development Result

The development phase results in a layered security setup where different roles control different operations and the READ operation additionally uses the Branch field and script logic.
